Infection.txt explanation

Once I used my binary decoder program on the infection.txt program, I got the following code snippet:

```
int main(int argc, char** argv)
{
	for (;;)
		system(argv[0]);
}
```

The code is a simple for loop that runs infinitely. I then tested it on my Debian VM. The result was the program running until I had to force the program to quit. I had the same result on my Windows host machine. The purpose and danger with this small program is to run in the background, using up resources and preventing other processes from working. Ways to prevent hackers from doing this are preventing them from accessing your machine in any way and not running any strange programs.
